Read me

So we're going to be creating a program to combat that.And it's going to be called MyPass, our password manager,and we're going to use it to store and generate passwords.For example, if I wanted to create an account on Instagram,then I enter the name of the website so that I know what th.is password is for,I put in my email, and username is already prepopulated in my password manager. And then all I have to do is to either come up with a password that is hopefully not terrible, but I can obviously never remember, or I can use the builtin generate password to just generate me a very complex,very long password with all of the required numbers and symbols and all of that.And once I'm done with that, then I can click add,and I get a popup asking me if this is okay.And if that all looks good, then I click Yes and that data gets added to a text file,which I have on my computer.So this is not an internet-based service and you keep everything locally on your computer.
